Octet Rule

Eight valence electrons, ns^2np^6 , is especially stable
Noble gases do not tend to form compounds

To reach stability of the octet:

Atoms lose or gain (transfer) electrons (for ionic compounds)

Atoms share electrons (for molecular or covalent bonded compounds)

Product: both atoms with "inert configuration"

LPT

Covalent Bond: Electrons Shared

Electron pair **BETWEEN** atoms implies sharing
Both atoms "noble"
Each shared pair = covalent bond

Copyright Larry P. Taylor, Ph.D. All Rights Reserved

LPT

Nomenclature – Line for pair

Example: Diatomic Halogen 

Step 1:  **Draw Valence Electrons**

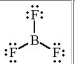

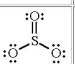

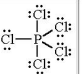

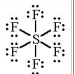

Step 2:  **Establish “share” or “transfer”**

Step 3:  **Connect “Share”**

Step 4:  **Can replace any 2 e⁻ with line**

Valence Shell Electron Pair Repulsion (VSEPR)

Central Atom Bonding Determines Molecular Shape

Number of electron bonding groups:

2	3	4	5	6
Linear	Trigonal-planar	Tetrahedral	Trigonal-bipyramidal	Octahedral
180°	120°	109.5°	120° and 90°	90°
AX_2 Example: BeF_2	AX_3 Example: BF_3	AX_4 Example: CF_4	AX_5 Example: PF_5	AX_6 Example: SF_6

VSEPR: Lone Pair Repulsion Finalizes Shape

# Groups	Bond angles	Spatial geometry	Electron pair geometry	Lone pair substitutions
2	180°	Linear	(sp)	
3	120°	Trigonal planar	(sp ²)	Bent
4	109.5°	Tetrahedral	(sp ³)	Trigonal pyramidal
5	90°, 120°	Trigonal bipyramidal	(sp ³ d)	"Seesaw", T-shaped, Linear
6	90°	Octahedral	(sp ³ d ²)	Square pyramidal, Square planar, T-shaped, Linear

LPT

Drawing Lewis Structures

SO3

Major pollutant in power plant emissions

$$\text{SO}_3 + \text{H}_2\text{O} \rightarrow \text{H}_2\text{SO}_4$$

Electronegativity:
S = 2.5
O = 3.5

Copyright Larry P. Taylor, Ph.D. All Rights Reserved

LPT

Step One: Determine Least Electronegative Atom

Least Polar Atom
Becomes Central
In Lewis Structure

H never Central

Electronegativity Differences
 $\Delta \leq 0.4$ → non-polar covalent
 $\Delta > 0.4 - 1.9$ → polar covalent
 $\Delta > 1.9$ → ionic
 Δ = difference in electronegativity of the bonded atoms

LPT

Copyright Larry P. Taylor, Ph.D. All Rights Reserved

Step Two: Calculate Valence Electrons for Each Atom

Sum the valence electrons of all the atoms in the unit
 Add one electron for each net negative charge
 Subtract one electron for each net positive charge

For SO_3 :

S = 6 electrons
 $\text{O} = (3 \times 6) = 18$ electrons
 Total = 24 electrons

Divide by 2 to get number of electron pairs
 $24 \text{ electrons} / 2 = 12 \text{ electron pairs}$

LPT

Copyright Larry P. Taylor, Ph.D. All Rights Reserved

Step Three: Distribute Electrons around Central Atom

One pair between the central atom and each ligand atom
 Central atom filled to octet
 Additional pairs on each outer atom (except hydrogen)

For SO_3 → Drawing to total of 12 pairs

Not Octet

Not all atoms have octet

LPT

Copyright Larry P. Taylor, Ph.D. All Rights Reserved

Step Four: Use “Formal Charge” to Resolve Octets
Need Formal Charge to be 0 on all atoms
or the charge on ionic species

$$\text{Formal Charge} = \# \text{ valence } e^- - (\# \text{ unshared } e^- + 0.5 * \text{ bonding } e^-)$$

For Sulfur (the central atom)

$$F = 6 (\text{group 6 atom}) - (2 + 3 (6/2))$$

$$F = 6 - 5 = +1$$

In terms of “molecular Psychology”

Sulfur not “happy” with a full +1 charge

Reduce formal charge with multiple bond formation

Copyright Larry P. Taylor, Ph.D. All Rights Reserved

LPT

Step Five: Add multiple bond to complete octet

Step Six: Recalculate Formal Charges

$$\text{Sulfur: } 6 - (0 + 4) = +2$$

$$\text{Oxygen in bottom row: } 6 - (6 + 1) = -1$$

$$\text{Oxygen at top: } 6 - (4 + 2) = 0$$

$$\text{Formal Charges balance: } 2 \times (-1) \text{ electrically balances } +2$$

LPT

Resonance

Concept used to explain observed bond lengths

Describes molecules where bonding cannot be expressed with a single Lewis Structure

Electrons assumed to be delocalized throughout the system

Result is defined as a “resonance hybrid” of several forms

Individual resonance structures do not exist
